

# The McNaughton Theorem

## McNaughton Theorem

**Theorem 1** *Let  $\Sigma$  be an alphabet. Any  $\omega$ -recognizable subset of  $\Sigma^\omega$  can be recognized by a Rabin automaton.*

Determinisation algorithm by S. Safra (1989) uses a special subset construction to obtain a Rabin automaton equivalent to a given Büchi automaton. The Safra algorithm is optimal  $2^{O(n \log n)}$ .

This proves that  $\omega$ -recognizable languages are closed under complement.

# Oriented Trees

Let  $\Sigma$  be an alphabet of labels.

An **oriented tree** is a pair of partial functions  $t = \langle l, s \rangle$ :

- $l : \mathbb{N} \mapsto \Sigma$  denotes the labels of the nodes
- $s : \mathbb{N} \mapsto \mathbb{N}^*$  gives the **ordered** list of children of each node

$$\text{dom}(l) = \text{dom}(s) \stackrel{\text{def}}{=} \text{dom}(t)$$

$p \leq q$ :  $q$  is a successor of  $p$  in  $t$

$p \preceq_{\text{left}} q$ :  $p$  is **to the left** of  $q$  in  $t$  ( $p \preceq q$  and  $p \not\leq q$ )

## Safra Trees

Let  $A = \langle S, I, T, F \rangle$  be a Büchi automaton.

A *Safra tree* is a pair  $\langle t, m \rangle$ , where  $t$  is a finite **oriented tree** labeled with non-empty subsets of  $S$ , and  $m \subseteq \text{dom}(t)$  is the set of *marked positions*, such that:

- each marked position is a leaf
- for each  $p \in \text{dom}(t)$ , the union of labels of its children is a strict subset of  $t(p)$
- for each  $p, q \in \text{dom}(t)$ , if  $p \not\leq q$  and  $q \not\leq p$  then  $t(p) \cap t(q) = \emptyset$

**Proposition 1** *A Safra tree has at most  $\|S\|$  nodes.*

$$r(p) = t(p) \setminus \bigcup_{q < p} t(q)$$

$$\|\text{dom}(t)\| = \sum_{p \in \text{dom}(t)} 1 \leq \sum_{p \in \text{dom}(t)} \|r(p)\| \leq \|S\|$$

## Initial State

We build a Rabin automaton  $B = \langle S_B, i_B, T_B, \Omega_B \rangle$ , where:

- $S_B$  is the set of all Safra trees  $\langle t, m \rangle$  labeled with subsets of  $S$
- $i_B = \langle t, m \rangle$  is the Safra tree defined as either:
  - $\text{dom}(t) = \{1\}, t(1) = I$  and  $m = \emptyset$  if  $I \cap F = \emptyset$
  - $\text{dom}(t) = \{1\}, t(1) = I$  and  $m = \{\epsilon\}$  if  $I \subseteq F$
  - $\text{dom}(t) = \{1, 2\}, t(1) = I, t(2) = I \cap F$  and  $m = \{2\}$  if  $I \cap F \neq \emptyset$

## Classical Subset Move

**[Step 1]**  $\langle t_1, m_1 \rangle$  is the tree with  $\text{dom}(t_1) = \text{dom}(t)$ ,  $m_1 = \emptyset$ , and  $t_1(p) = \{s' \mid s \xrightarrow{\alpha} s', s \in t(p)\}$ , for all  $p \in \text{dom}(t)$

## Spawn New Children

**[Step 2]**  $\langle t_2, m_2 \rangle$  is the tree such that, for each  $p \in \text{dom}(t_1)$ , if  $t_1(p) \cap F \neq \emptyset$  we **add a new child to the right**, identified by the first available id, and labeled  $t_1(p) \cap F$ , and  $m_2$  is the set of all such children

# Horizontal Merge

**[Step 3]**  $\langle t_3, m_3 \rangle$  is the tree with  $\text{dom}(t_3) = \text{dom}(t_2)$ ,  $m_3 = m_2$ , such that,  
for all  $p \in \text{dom}(t_3)$ ,  $t_3(p) = t_2(p) \setminus \bigcup_{q \prec_{\text{left}} p} t_2(q)$

## Delete Empty Nodes

[Step 4]  $\langle t_4, m_4 \rangle$  is the tree such that  $\text{dom}(t_4) = \text{dom}(t_3) \setminus \{p \mid t_3(p) = \emptyset\}$   
and  $m_4 = m_3 \setminus \{p \mid t_3(p) = \emptyset\}$

## Vertical Merge

[Step 5]  $\langle t_5, m_5 \rangle$  is  $m_5 = m_4 \cup V$ ,  $dom(t_5) = dom(t_4) \setminus \{q \mid p \in V, p < q\}$ ,  
 $V = \{p \in dom(t_4) \mid t_4(p) = \bigcup_{p < q} t_4(q)\}$

## Accepting Condition

The Rabin accepting condition is defined as

$\Omega_B = \{(N_q, P_q) \mid q \in \bigcup_{\langle t, m \rangle \in S_B} \text{dom}(t)\}$ , where:

- $N_q = \{\langle t, m \rangle \in S_B \mid q \notin \text{dom}(t)\}$
- $P_q = \{\langle t, m \rangle \in S_B \mid q \in m\}$

$$\Omega_B = \{(\{R_1\}, \{R_2\}), (\{R_2\}, \{R_1\})\}$$

# Example

# Correctness of Safra Construction

**Lemma 1** For  $0 \leq i \leq n - 1$ ,  $S_{i+1} \subseteq T(S_i, \alpha_{i+1})$ . Moreover, for every  $q \in S_n$ , there is a path in  $A$  starting in some  $q_0 \in S_0$ , ending in  $q$  and visiting at least one final state *after its origin*.

An infinite accepting path in  $B$  corresponds to an infinite accepting path in  $A$  (König's Lemma)

## Correctness of Safra Construction

Conversely, an infinite accepting path of  $A$  over  $u = \alpha_0\alpha_1\alpha_2 \dots$

$$\pi : q_0 \xrightarrow{\alpha_0} q_1 \xrightarrow{\alpha_1} q_2 \dots$$

corresponds to a **unique** infinite path of  $B$ :

$$i_B = R_0 \xrightarrow{\alpha_0} R_1 \xrightarrow{\alpha_1} R_2 \dots$$

where each  $q_i$  belongs to the root of  $R_i$

If the root is marked infinitely often, then  $u$  is accepted. Otherwise, let  $n_0$  be the largest number such that the root is marked in  $R_{n_0}$ . Let  $m > n_0$  be the smallest number such that  $q_m \in F$  is repeated infinitely often in  $\pi$ .

Since  $q_m \in F$  it appears in a child of the root. If it appears always on the same position  $p_m$ , then the path is accepting. Otherwise it appears to the left of  $p_m$  from some  $n_1$  on (step 3). This left switch can only occur a finite number of times.

## Complexity of the Safra Construction

Given a Büchi automaton with  $n$  states, how many states we need for an equivalent Rabin automaton?

- The **upper bound** is  $2^{\mathcal{O}(n \log n)}$  states
- The **lower bound** is of at least  $n!$  states

## Maximum Number of Safra Trees

Each Safra tree has at most  $n$  nodes.

A Safra tree  $\langle t, m \rangle$  can be uniquely described by the functions:

- $S \rightarrow \{0, \dots, n\}$  gives for each  $s \in S$  the **characteristic position**  $p \in \text{dom}(t)$  such that  $s \in t(p)$ , and  $s$  does not appear below  $p$
- $\{1, \dots, n\} \rightarrow \{0, 1\}$  is the **marking function**
- $\{1, \dots, n\} \rightarrow \{0, \dots, n\}$  is the **parent function**
- $\{1, \dots, n\} \rightarrow \{0, \dots, n\}$  is the **older brother function**

Altogether we have at most  $(n+1)^n \cdot 2^n \cdot (n+1)^n \cdot (n+1)^n \leq (n+1)^{4n}$  Safra trees, hence the upper bound is  $2^{\mathcal{O}(n \log n)}$ .

## The Language $L_n$

$$\Sigma = \{1, \dots, n, \#\}$$

$$(3\#32\#21\#1)^\omega \in L_3$$

$$(312\#)^\omega \notin L_3$$

$\alpha \in L_n$  iff there exist  $i_1, \dots, i_n \in \{1, \dots, n\}$  such that

- $\alpha_k = i_1$  is the first occurrence of  $i_1$  in  $\alpha$  and  $q_0 \xrightarrow{\alpha_0 \dots \alpha_k} q_{i_1}$
- the pairs  $i_1 i_2, i_2 i_3, \dots, i_n i_1$  appear infinitely often in  $\alpha$ .

## The Language $L_n$

**Lemma 2** (*Permutation*) For each permutation  $i_1, i_2, \dots, i_n$  of  $1, 2, \dots, n$ , the infinite word  $(i_1 i_2 \dots i_n \#)^\omega \notin L_n$ .

**Lemma 3** (*Union*) Let  $A = (S, i, T, \Omega)$  be a Rabin automaton with  $\Omega = \{\langle N_1, P_1 \rangle, \dots, \langle N_k, P_k \rangle\}$  and  $\rho_1, \rho_2, \rho$  be runs of  $A$  such that

$$\text{inf}(\rho_1) \cup \text{inf}(\rho_2) = \text{inf}(\rho)$$

If  $\rho_1$  and  $\rho_2$  are not successful, then  $\rho$  is not successful either.

## Proving the $n!$ Lower Bound

Suppose that  $A$  recognizes  $L_n$ . We need to show that  $A$  has  $\geq n!$  states.

Let  $\alpha = i_1, i_2, \dots, i_n$  and  $\beta = j_1, j_2, \dots, j_n$  be two permutations of  $1, 2, \dots, n$ . Then the words  $(i_1 i_2 \dots i_n \#)^\omega$  and  $(j_1 j_2 \dots j_n \#)^\omega$  are not accepted.

Let  $\rho_\alpha, \rho_\beta$  be the non-accepting runs of  $A$  over  $\alpha$  and  $\beta$ , respectively.

**Claim 1**  $\inf(\rho_\alpha) \cap \inf(\rho_\beta) = \emptyset$

Then  $A$  must have  $\geq n!$  states, since there are  $n!$  permutations.

## Proving the $n!$ Lower Bound

By contradiction, assume  $q \in \inf(\rho_\alpha) \cap \inf(\rho_\beta)$ . Then we can build a run  $\rho$  such that  $\inf(\rho) = \inf(\rho_1) \cup \inf(\rho_2)$  and  $\alpha, \beta$  appear infinitely often. By the union lemma,  $\rho$  is not accepting.

$$\begin{array}{cccccccccccc}
 i_1 & \dots & i_{k-1} & \textcolor{red}{i_k} & i_{k+1} & \dots & i_{l-1} & \textcolor{green}{i_l} & \dots & & i_n \\
 = & & = & \neq & & & & & & & \\
 j_1 & \dots & j_{k-1} & \textcolor{green}{j_k} & j_{k+1} & \dots & & j_{r-1} & \textcolor{red}{j_r} & \dots & j_n
 \end{array}$$

---

$$i_k \quad i_{k+1}, \quad \dots \quad i_l = j_k \quad j_{k+1}, \quad \dots \quad j_{r-1}, \quad j_r = i_k$$

The new word is accepted since the pairs  $i_k i_{k+1}, \dots, j_k j_{k+1}, \dots, j_{r-1} i_k$  occur infinitely often. Contradiction with the fact that  $\rho$  is not accepting.

# Linear Temporal Logic

## Safety vs. Liveness

- **Safety** : *something bad never happens*

A counterexample is an **finite** execution leading to something bad happening (e.g. an assertion violation).

- **Liveness** : *something good eventually happens*

A counterexample is an **infinite** execution on which nothing good happens (e.g. the program does not terminate).

# Verification of Reactive Systems

- Classical verification à la Floyd-Hoare considered three problems:

- **Partial Correctness** :

$\{\varphi\} \mathbf{P} \{\psi\}$  iff for any  $s \models \varphi$ , if  $P$  terminates on  $s$ , then  $P(s) \models \psi$

- **Total Correctness** :

$\{\varphi\} \mathbf{P} \{\psi\}$  iff for any  $s \models \varphi$ ,  $P$  terminates on  $s$  and  $P(s) \models \psi$

- **Termination** :

$P$  terminates on  $s$

- Need to reason about **infinite computations** :

- systems that are in continuous interaction with their environment

- servers, control systems, etc.

- e.g. *“every request is eventually answered”*

## Reasoning about infinite sequences of states

- Linear Temporal Logic is interpreted on **infinite sequences of states**
- Each state in the sequence gives an interpretation to the **atomic propositions**
- **Temporal operators** indicate in which states a formula should be interpreted

*Example 1 Consider the sequence of states:*

$$\{p, q\} \ \{\neg p, \neg q\} \ (\{\neg p, q\} \ \{p, q\})^\omega$$

*Starting from position 2,  $q$  holds forever.  $\square$*

# Kripke Structures

Let  $\mathcal{P} = \{p, q, r, \dots\}$  be a finite alphabet of *atomic propositions*.

A *Kripke structure* is a tuple  $K = \langle S, s_0, \rightarrow, L \rangle$  where:

- $S$  is a set of *states*,
- $s_0 \in S$  a designated *initial state*,
- $\rightarrow : S \times S$  is a *transition relation*,
- $L : S \rightarrow 2^{\mathcal{P}}$  is a *labeling function*.

## Paths in Kripke Structures

A *path* in  $K$  is an *infinite* sequence  $\pi : s_0, s_1, s_2 \dots$  such that, for all  $i \geq 0$ , we have  $s_i \rightarrow s_{i+1}$ .

By  $\pi(i)$  we denote the  $i$ -th state on the path.

By  $\pi_i$  we denote the *suffix*  $s_i, s_{i+1}, s_{i+2} \dots$

$$\inf(\pi) = \{s \in S \mid s \text{ appears infinitely often on } \pi\}$$

If  $S$  is *finite* and  $\pi$  is *infinite*, then  $\inf(\pi) \neq \emptyset$ .

# Linear Temporal Logic: Syntax

The alphabet of LTL is composed of:

- atomic proposition symbols  $p, q, r, \dots$ ,
- boolean connectives  $\neg, \vee, \wedge, \rightarrow, \leftrightarrow$ ,
- temporal connectives  $\bigcirc, \square, \diamond, \mathcal{U}, \mathcal{R}$ .

The set of LTL formulae is defined inductively, as follows:

- any atomic proposition is a formula,
- if  $\varphi$  and  $\psi$  are formulae, then  $\neg\varphi$  and  $\varphi \bullet \psi$ , for  $\bullet \in \{\vee, \wedge, \rightarrow, \leftrightarrow\}$  are also formulae.
- if  $\varphi$  and  $\psi$  are formulae, then  $\bigcirc\varphi, \square\varphi, \diamond\varphi, \varphi\mathcal{U}\psi$  and  $\varphi\mathcal{R}\psi$  are formulae,
- nothing else is a formula.

# Temporal Operators

- $\bigcirc$  is read **at the next time** (in the next state)
- $\Box$  is read **always in the future** (in all future states)
- $\Diamond$  is read **eventually** (in some future state)
- $\mathcal{U}$  is read **until**
- $\mathcal{R}$  is read **releases**

## Linear Temporal Logic: Semantics

$$\begin{aligned} K, \pi \models p & \iff p \in L(\pi(0)) \\ K, \pi \models \neg\varphi & \iff K, \pi \not\models \varphi \\ K, \pi \models \varphi \wedge \psi & \iff K, \pi \models \varphi \text{ and } K, \pi \models \psi \\ K, \pi \models \bigcirc\varphi & \iff K, \pi_1 \models \varphi \\ K, \pi \models \varphi\mathcal{U}\psi & \iff \text{there exists } k \in \mathbb{N} \text{ such that } K, \pi_k \models \psi \\ & \text{and } K, \pi_i \models \varphi \text{ for all } 0 \leq i < k \end{aligned}$$

Derived meanings:

$$\begin{aligned} K, \pi \models \Diamond\varphi & \iff K, \pi \models \top\mathcal{U}\varphi \\ K, \pi \models \Box\varphi & \iff K, \pi \models \neg\Diamond\neg\varphi \\ K, \pi \models \varphi\mathcal{R}\psi & \iff K, \pi \models \neg(\neg\varphi\mathcal{U}\neg\psi) \end{aligned}$$

## Examples

- $p$  holds throughout the execution of the system ( $p$  is **invariant**) :  $\Box p$
- whenever  $p$  holds,  $q$  is **bound to hold in the future** :  $\Box(p \rightarrow \Diamond q)$
- $p$  holds infinitely often :  $\Box \Diamond p$
- $p$  holds forever starting from a certain point in the future :  $\Diamond \Box p$
- $\Box(p \rightarrow \bigcirc(\neg q \mathcal{U} r))$  holds in all sequences such that if  $p$  is true in a state, then  $q$  remains false from the next state and until the first state where  $r$  is true, which must occur.
- $p\mathcal{R}q$  :  $q$  is true unless this obligation is **released** by  $p$  being true in a previous state.

## LTL vs. FOL

**Theorem 2** *LTL and FOL on infinite words have the same expressive power.*

From LTL to FOL:

$$\begin{aligned} Tr(q) &= p_q(t) \\ Tr(\neg\varphi) &= \neg Tr(\varphi) \\ Tr(\varphi \wedge \psi) &= Tr(\varphi) \wedge Tr(\psi) \\ Tr(\bigcirc\varphi) &= Tr(\varphi)[t + 1/t] \\ Tr(\varphi\mathcal{U}\psi) &= \exists x . Tr(\psi)[x/t] \wedge \forall y . y < x \rightarrow Tr(\varphi)[y/t] \end{aligned}$$

The direction from FOL to LTL is known as Kamp's Theorem.

# LTL Model Checking

## System verification using LTL

- Let  $K$  be a model of a reactive system (finite computations can be turned into infinite ones by repeating the last state infinitely often)
- Given an LTL formula  $\varphi$  over a set of atomic propositions  $\mathcal{P}$ , specifying all **bad** behaviors, we build a Büchi automaton  $A_\varphi$  that accepts all sequences over  $2^{\mathcal{P}}$  satisfying  $\varphi$ .

**Q:** Since  $\text{LTL} \subset \text{S1S}$ , this automaton can be built, so why bother?

- Check whether  $\mathcal{L}(A_\varphi) \cap \mathcal{L}(K) = \emptyset$ . In case it is not, we obtain a **counterexample**.

# Generalized Büchi Automata

Let  $\Sigma = \{a, b, \dots\}$  be a finite alphabet.

A *generalized Büchi automaton* (GBA) over  $\Sigma$  is  $A = \langle S, I, T, \mathcal{F} \rangle$ , where:

- $S$  is a finite set of *states*,
- $I \subseteq S$  is a set of *initial states*,
- $T \subseteq S \times \Sigma \times S$  is a *transition relation*,
- $\mathcal{F} = \{F_1, \dots, F_k\} \subseteq 2^S$  is a set of *sets of final states*.

A run  $\pi$  of a GBA is said to be *accepting* iff, for all  $1 \leq i \leq k$ , we have

$$\text{inf}(\pi) \cap F_i \neq \emptyset$$

## GBA and BA are equivalent

Let  $A = \langle S, I, T, \mathcal{F} \rangle$ , where  $\mathcal{F} = \{F_1, \dots, F_k\}$ .

Build  $A' = \langle S', I', T', F' \rangle$ :

- $S' = S \times \{1, \dots, k\}$ ,
- $I' = I \times \{1\}$ ,
- $(\langle s, i \rangle, a, \langle t, j \rangle) \in T'$  iff  $(s, t) \in T$  and:
  - $j = i$  if  $s \notin F_i$ ,
  - $j = (i \bmod k) + 1$  if  $s \in F_i$ .
- $F' = F_1 \times \{1\}$ .

## The idea of the construction

Let  $K = \langle S, s_0, \rightarrow, L \rangle$  be a Kripke structure over a set of atomic propositions  $\mathcal{P}$ ,  $\pi : \mathbb{N} \rightarrow S$  be an infinite path through  $K$ , and  $\varphi$  be an LTL formula.

To determine whether  $K, \pi \models \varphi$ , we label  $\pi$  with sets of subformulae of  $\varphi$  in a way that is compatible with LTL semantics.

## Closure

Let  $\varphi$  be an LTL formula written in **negation normal form**.

The **closure** of  $\varphi$  is the set  $Cl(\varphi) \in 2^{\mathcal{L}(LTL)}$ :

- $\varphi \in Cl(\varphi)$
- $\bigcirc\psi \in Cl(\varphi) \Rightarrow \psi \in Cl(\varphi)$
- $\psi_1 \bullet \psi_2 \in Cl(\varphi) \Rightarrow \psi_1, \psi_2 \in Cl(\varphi)$ , for all  $\bullet \in \{\wedge, \vee, \mathcal{U}, \mathcal{R}\}$ .

*Example 2*  $Cl(\diamond p) = Cl(\top \mathcal{U} p) = \{\diamond p, p, \top\} \square$

**Q:** What is the size of the closure relative to the size of  $\varphi$  ?

## Labeling rules

Given  $\pi : \mathbb{N} \rightarrow 2^{\mathcal{P}}$  and  $\varphi$ , we define  $\tau : \mathbb{N} \rightarrow 2^{Cl(\varphi)}$  as follows:

- for  $p \in \mathcal{P}$ , if  $p \in \tau(i)$  then  $p \in \pi(i)$ , and if  $\neg p \in \tau(i)$  then  $p \notin \pi(i)$
- if  $\psi_1 \wedge \psi_2 \in \tau(i)$  then  $\psi_1 \in \tau(i)$  and  $\psi_2 \in \tau(i)$
- if  $\psi_1 \vee \psi_2 \in \tau(i)$  then  $\psi_1 \in \tau(i)$  or  $\psi_2 \in \tau(i)$

## Labeling rules

$$\varphi\mathcal{U}\psi \iff \psi \vee (\varphi \wedge \bigcirc(\varphi\mathcal{U}\psi))$$

$$\varphi\mathcal{R}\psi \iff \psi \wedge (\varphi \vee \bigcirc(\varphi\mathcal{R}\psi))$$

- if  $\bigcirc\psi \in \tau(i)$  then  $\psi \in \tau(i+1)$
- if  $\psi_1\mathcal{U}\psi_2 \in \tau(i)$  then **either**  $\psi_2 \in \tau(i)$ , or  $\psi_1 \in \tau(i)$  and  $\psi_1\mathcal{U}\psi_2 \in \tau(i+1)$
- if  $\psi_1\mathcal{R}\psi_2 \in \tau(i)$  then  $\psi_2 \in \tau(i)$  **and either**  $\psi_1 \in \tau(i)$  or  $\psi_1\mathcal{R}\psi_2 \in \tau(i+1)$

## Interpreting labelings

A sequence  $\pi$  satisfies a formula  $\varphi$  if one can find a labeling  $\tau$  satisfying:

- the labeling rules above
- $\varphi \in \tau(0)$ , and
- if  $\psi_1 \mathcal{U} \psi_2 \in \tau(i)$ , then for some  $j \geq i$ ,  $\psi_2 \in \tau(j)$  (the eventuality condition)

## Building the GBA $A_\varphi = \langle S, I, T, \mathcal{F} \rangle$

The automaton  $A_\varphi$  is the set of labeling rules + the eventuality condition(s) !

- $\Sigma = 2^{\mathcal{P}}$  is the alphabet
- $S \subseteq 2^{Cl(\varphi)}$ , such that, **for all  $s \in S$**  :
  - $\varphi_1 \wedge \varphi_2 \in s \Rightarrow \varphi_1 \in s$  and  $\varphi_2 \in s$
  - $\varphi_1 \vee \varphi_2 \in s \Rightarrow \varphi_1 \in s$  or  $\varphi_2 \in s$
- $I = \{s \in S \mid \varphi \in s\}$ ,
- $(s, \alpha, t) \in T$  iff:
  - for all  $p \in \mathcal{P}$ ,  $p \in s \Rightarrow p \in \alpha$ , and  $\neg p \in s \Rightarrow p \notin \alpha$ ,
  - $\bigcirc \psi \in s \Rightarrow \psi \in t$ ,
  - $\psi_1 \mathcal{U} \psi_2 \in s \Rightarrow \psi_2 \in s$  or  $[\psi_1 \in s \text{ and } \psi_1 \mathcal{U} \psi_2 \in t]$
  - $\psi_1 \mathcal{R} \psi_2 \in s \Rightarrow \psi_2 \in s$  and  $[\psi_1 \in s \text{ or } \psi_1 \mathcal{R} \psi_2 \in t]$

## Building the GBA $A_\varphi = \langle S, I, T, \mathcal{F} \rangle$

- for each **eventuality**  $\phi\mathcal{U}\psi \in Cl(\varphi)$ , the transition relation ensures that this will appear until the first occurrence of  $\psi$
- it is sufficient to ensure that, for each  $\phi\mathcal{U}\psi \in Cl(\varphi)$ , one goes infinitely often either through a state **in which this does not appear**, or through a state **in which both  $\phi\mathcal{U}\psi$  and  $\psi$  appear**
- let  $\phi_1\mathcal{U}\psi_1, \dots, \phi_n\mathcal{U}\psi_n$  be the “until” subformulae of  $\varphi$

$\mathcal{F} = \{F_1, \dots, F_n\}$ , where:

$$F_i = \{s \in S \mid \phi_i\mathcal{U}\psi_i \in s \text{ and } \psi_i \in s \text{ or } \phi_i\mathcal{U}\psi_i \notin s\}$$

for all  $1 \leq i \leq n$ .
